Syntax of SMT(NRA)

polynomial: $p ::= x \mid c \mid p + p \mid p - p \mid p \times p$

atoms: $a ::= b \mid p = 0 \mid p > 0 \mid p < 0$

formula: $f ::= a \mid \neg f \mid f \wedge f \mid f \vee f$

SMT: Determine whether the formula is satisfied by some assignment (local search focuses), or prove unsat

Example:

$$x^2 + y^2 \leq 1 \wedge x + y < 1 \wedge x + z > 0$$

assignment with $\{x \rightarrow 0, y \rightarrow 0, z \rightarrow 1\}$ satisfies all clauses.

Fragment of Local Search

Input : A set of clauses F

Output: An assignment of variables that satisfy F ,
or failure

Initialize assignment to variables;

while \top **do**

if *all clauses satisfied* **then**

return *success with assignment*;

end

if *time or step limit reached* **then**

return *failure*;

end

 Critical move procedure.

end

Algorithm 1: Basic Fragment of Local Search

Fragment of Local Search

```
var, new_value, score  $\leftarrow$  best move according to  
make-break score;  
if score  $> 0$  then  
| Perform move, assigning var to new_value;  
end  
else  
| Update clause weight according to PAWS  
| scheme;  
| repeat  
| | cls  $\leftarrow$  random unsatisfied clause;  
| | var, new_value, score  $\leftarrow$  critical move  
| | making cls satisfied;  
| | if score  $\neq -\infty$  then  
| | | Perform move, assigning var to  
| | | new_value;  
| | end
```

Local Search for SAT and SMT

Problem \ LS	SAT	SMT
Operation (Move)	Flip	Critical Move
Score Definition	Weighted unsat clauses	
Score Computation	Cached score	No Caching, time costly

What LS for SAT brings us:

Maintain scoring information after each iteration.

Difficulty:

Predetermine critical move shift value.

Our Solution:

Introduce Scoring Boundaries.

Outline

1. Problem - Nonlinear Real Arithmetic
 - Search Space of SMT(NRA)
 - Current Existing Methods
2. Incremental Computation of Variable Scores
 - Scoring Boundary for Arithmetic Variable
 - Incremental Computation
3. Temporary Relaxation of Equality Constraints
 - Difficulty in Local Search
 - Relaxation Method
4. Experiment

Make-break Intervals

make-break intervals¹

Combination of (in)feasible intervals of arithmetic variable x with respect to all clauses.

Example

Current assignment: $\{x \mapsto 1, y \mapsto 1, z \mapsto 1\}$

Calculate infeasible set for each clause.

- $x^2 + y^2 \leq 1$ (unsat): $(-\infty, 0) \cup (0, \infty)$.
- $x + y < 1$ (unsat): $[0, \infty)$.
- $x + z > 0$ (sat): $(-\infty, -1]$.

Combined information: x : $(-\infty, -1] \mapsto 0$, $(-1, 0) \mapsto 1$, $[0, 0] \mapsto 1$, $(0, \infty) \mapsto 0$.

Traditional Computation

Input : unsat clauses F

Output: Best critical move (variable, value)

foreach *variable* v *in unsat clauses* **do**

foreach *unsat clause* c *with* v **do**

 | Compute interval-score info of v in c .

end

 Combine interval-score information.

 Update best var-value move.

end

return *best critical move*

Repeated computation:

- variable's (in)feasible set
- clause's sat status

Boundary

Definition. A quadruple $\langle val, is_open, is_make, cid \rangle$, where val is a real number, is_open and is_make are boolean values, and cid is a clause identifier.

Meaning

- val : make-break value.
- is_open : active or not at val point.
- is_make : make or break, increase or decrease score.
- cid : causing clause.

Sorting First ordered by val , then by is_open ($\perp < \top$).

Boundary

Current assignment: $\{x \mapsto 1, y \mapsto 1, z \mapsto 1\}$

- $x^2 + y^2 \leq 1$: starting score 0, boundary set $\{(0, \perp, \top, 1), (0, \top, \perp, 1)\}$, indicating no change for large negative values, *make* at boundary $[0, \dots$, followed by *break* at boundary $(0, \dots$.
- $x + y < 1$: starting score 3, boundary set $\{(0, \perp, \perp, 2)\}$, indicating *make* at large negative values, and *break* at boundary $[0, \dots$.
- $x + z > 0$: starting score -2 , boundary set $\{(-1, \top, \top, 3)\}$, indicating *break* at large negative values, and *make* at boundary $(-1, \dots$.

sorted boundary set:

$\{(-1, \top, \top, 3), (0, \perp, \top, 1), (0, \perp, \perp, 2), (0, \top, \perp, 1)\}$

Boundary Example

boundary set:

$$\{(-1, \top, \top, 3), (0, \perp, \top, 1), (0, \perp, \perp, 2), (0, \top, \perp, 1)\}$$

starting score: Score when x moves to $-\infty$.

Maintain and Change: We maintain the boundary info for all arithmetic variables, unless the neighbour does a critical move.

Algorithm for computing boundary

Input : Variable v that is modified

Output: Make-break score for all variables

$S \leftarrow \{\}$; // set of updated variables

for *clause* cls *that contains* v **do**

for *variable* v' *appearing in* cls **do**

 add v' to S ;

 recompute starting score and boundary of v'
 with respect to cls ;

end

end

for *variable* v' *in* S **do**

 recompute best critical move and score in terms
 of boundary information;

end

4. Experiment

Previous Algorithm and Difficulty

Number complexation in Local Search

When a variable chooses a complex value, the iteration is much slower, but sometimes we have to ...

Reference² ignores equalities constraints due to its accurate value complexation.

We introduce Relaxation into strick equality constraints, resulting in temporary interval candidate (rather than a point).

Local Search with Relaxation

Input : A set of clauses F

Output: An assignment of variables that satisfy F , or failure

Initialize assignment to variables;

while \top **do**

if *all clauses satisfied* **then**

$success \leftarrow$ find exact solution;

if *success* **then**

return *success with assignment*;

end

else

 Restore relaxed constraints to original form;

$success \leftarrow$ find exact solution by limited local search;

if *success* **then**

return *success with assignment*;

end

end

end

if *time or step limit reached* **then**

return *failure*;

end

 Proceed traditional local search (slack).

end
